Sum of amount (INR) by transaction type and sender_age_group

Count of transaction_status by transaction_status, device_type and network_type

device_type ● Android ● iOS ● Web

Sum of amount (INR) by hour_of_day and day_of_week

day_of_week ● Friday ● Monday ● Saturday ● Sunday ● Thursday ● Tuesday ● Wednesday

1) The stacked column chart shows transaction volume and value distribution across mobile devices by age group. Android users aged 26–35 account for the highest share of transactions, while web users above 56 contribute the lowest. This suggests stronger adoption of mobile-first banking behavior among younger users, while older demographics show limited engagement with web-based platforms. This also indicates that this segment is the primary driver of revenue within the platform. This suggests that optimizing mobile performance and targeting this demographic could significantly enhance transaction growth and overall revenue generation.

2) The stacked bar chart compares transaction success rates across device types and network conditions. Android users consistently show higher success rates across all network types (3G, 4G, 5G, Wi-Fi), while web-based transactions record the lowest success rate. This indicates stronger reliability and user experience on mobile applications compared to browser-based access. This also shows that higher transaction success rates on Android devices directly translate to increased revenue realization, while lower success rates on web platforms indicate potential revenue leakage due to failed transactions. Improving web transaction reliability could recover lost revenue and enhance overall system efficiency.

3) The treemap highlights transaction type distribution across age groups, with peer-to-peer (P2P) transfers being the dominant transaction type across all demographics. Recharge payments represent the smallest proportion of transactions, indicating lower engagement with utility-based or prepaid services compared to money transfers. Peer-to-peer (P2P) transactions dominate overall volume, making them a key contributor to transaction-based revenue streams. In contrast, the low share of recharge transactions suggests underutilization of alternative revenue channels, presenting an opportunity to diversify transaction types and increase monetization.

4) The ribbon chart illustrates transaction volume patterns across hours and days of the week. Activity peaks at 7 PM (19th hour) on Mondays, while the lowest activity occurs at 3 AM on Tuesdays. This indicates higher user engagement during evening hours, likely aligned with post-work activity periods. Transaction activity peaks during evening hours (around 7 PM), represent periods of highest revenue generation and system demand thereby highlights the need for optimized system performance and capacity planning during peak hours to prevent **transaction failures and potential revenue loss.**
